NE-1050

ABSTRACT OF THE DISCLOSURE

1   In a client-server system, the browser of a client terminal transmits a

2   first request packet to a server. The server, in response, transmits server

3   specific information to the browser for indicating a server in which shared

4   data file is maintained. The browser responds to the server specific

5   information for invoking the processor of the client terminal to hand over the

6   received information. When invoked, the processor transmits a second

7   request packet to a server specified by the received information to download

8   the shared data file from the server. If the shared data file were transferred to

9   a different server, the server specific information would be updated so that

10   the client terminal can accesses the new server to obtain the data file.
